Differential Operators, Harmonic Oscillators

Reading:

Kreyszig Sections: §2.4 (pp:81–83) , §2.5 (pp:83–89) , §2.8 (pp:101–03)

Differential Operators

The idea of a function as “something” that takes a value (real, complex, vector, etc.) as “input” and returns “something else” as “output” should be very familiar and useful.

This idea can be generalized to *operators* that take a function as an argument and return another function.

The derivative operator operates on a function and returns another function that describes how the function changes:

$$\begin{aligned}\mathcal{D}[f(x)] &= \frac{df}{dx} \\ \mathcal{D}[\mathcal{D}[f(x)]] &= \mathcal{D}^2[f(x)] = \frac{d^2 f}{dx^2} \\ \mathcal{D}^n[f(x)] &= \frac{d^n f}{dx^n} \\ \mathcal{D}[\alpha f(x)] &= \alpha \mathcal{D}[f(x)] \\ \mathcal{D}[f(x) + g(x)] &= \mathcal{D}[f(x)] + \mathcal{D}[g(x)]\end{aligned}\tag{22-1}$$

The last two equations above indicate that the “differential operator” is a linear operator.

The integration operator is the right-inverse of $\mathcal{D}$

$$\mathcal{D}[\mathcal{I}[f(x)]] = \mathcal{D}\left[\int f(x)dx\right]\tag{22-2}$$

but is only the left-inverse up to an arbitrary constant.

Consider the differential operator that returns a constant multiplied by itself

$$\mathcal{D}f(x) = \lambda f(x)\tag{22-3}$$

which is another way to write the the homogenous linear first-order ODE and has the same form as an eigenvalue equation. In fact, $f(x) = \exp(\lambda x)$, can be considered an *eigenfunction* of Eq. 22-3.

For the homogeneous second-order equation,

$$(\mathcal{D}^2 + \beta\mathcal{D} - \gamma) [f(x)] = 0\tag{22-4}$$

It was determined that there were two eigensolutions that can be used to span the entire solution space:

$$f(x) = C_+ e^{\lambda_+ x} + C_- e^{\lambda_- x}\tag{22-5}$$

Operators can be used algebraically, consider the inhomogeneous second-order ODE

$$(a\mathcal{D}^2 + b\mathcal{D} + c) [y(x)] = x^3\tag{22-6}$$

By treating the operator as an algebraic quantity, a solution can be found¹¹

$$\begin{aligned} y(x) &= \left(\frac{1}{a\mathcal{D}^2 + b\mathcal{D} + c} \right) [x^3] \\ &= \left(\frac{1}{c} - \frac{b}{c^2}\mathcal{D} + \frac{b^2 - ac}{c^3}\mathcal{D}^2 - \frac{b(b^2 - 2ac)}{c^3}\mathcal{D}^3 + \mathcal{O}(\mathcal{D}^4) \right) x^3 \\ &= \frac{x^3}{c} - \frac{3bx^2}{c^2} + \frac{6(b^2 - ac)x}{c^3} - \frac{6b(b^2 - 2ac)}{c^3} \end{aligned} \quad (22-7)$$

which solves Eq. 22-6.

The Fourier transform is also a linear operator:

$$\begin{aligned} \mathcal{F}[f(x)] &= g(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) e^{ikx} dx \\ \mathcal{F}^{-1}[g(k)] &= f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(k) e^{-ikx} dk \end{aligned} \quad (22-8)$$

Combining operators is another useful way to solve differential equations. Consider the Fourier transform, $\mathcal{F}$, operating on the differential operator, $\mathcal{D}$:

$$\mathcal{F}[\mathcal{D}[f]] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{df(x)}{dx} e^{ikx} dx \quad (22-9)$$

Integrating by parts,

$$= \frac{1}{\sqrt{2\pi}} f(x) \Big|_{x=-\infty}^{x=\infty} - \frac{ik}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) e^{ikx} dx \quad (22-10)$$

If the Fourier transform of $f(x)$ exists, then *typically*¹² $\lim_{x \rightarrow \pm\infty} f(x) = 0$. In this case,

$$\mathcal{F}[\mathcal{D}[f]] = -ik\mathcal{F}[f(x)] \quad (22-11)$$

and by extrapolation:

$$\begin{aligned} \mathcal{F}[\mathcal{D}^2[f]] &= -k^2\mathcal{F}[f(x)] \\ \mathcal{F}[\mathcal{D}^n[f]] &= (-1)^n i^n k^n \mathcal{F}[f(x)] \end{aligned} \quad (22-12)$$

☹ Operational Solutions to ODEs

Consider the heterogeneous second-order linear ODE which represent a forced, damped, harmonic oscillator that will be discussed later in this lecture.

$$M \frac{d^2 y(t)}{dt^2} + V \frac{dy(t)}{dt} + K_s y(t) = \cos(\omega_o t) \quad (22-13)$$

¹¹This method can be justified by plugging back into the original equation and verifying that the result is a solution.

¹² It is not necessary that $\lim_{x \rightarrow \pm\infty} f(x) = 0$ for the Fourier transform to exist but it is satisfied in most every case. The condition that the Fourier transform exists is that

$$\int_{-\infty}^{\infty} |f(x)| dx$$

exists and is bounded.

Apply a Fourier transform (mapping from the time (t) domain to a frequency (ω) domain) to both sides of 22-13:

$$\begin{aligned} \mathcal{F}\left[M\frac{d^2y(t)}{dt^2} + V\frac{dy(t)}{dt} + K_s y(t)\right] &= \mathcal{F}[\cos(\omega_o t)] \\ -M\omega^2 \mathcal{F}[y] - i\omega V \mathcal{F}[y] + K_s \mathcal{F}[y] &= \sqrt{\frac{\pi}{2}} [\delta(\omega - \omega_o) + \delta(\omega + \omega_o)] \end{aligned} \quad (22-14)$$

because the Dirac Delta functions result from taking the Fourier transform of $\cos(\omega_o t)$.

Equation 22-14 can be solved for the Fourier transform:

$$\mathcal{F}[y] = \sqrt{\frac{-\pi}{2}} \frac{[\delta(\omega - \omega_o) + \delta(\omega + \omega_o)]}{M\omega^2 + i\omega V - K_s} \quad (22-15)$$

In other words, the particular solution Eq. 22-13 can be obtained by finding the function $y(t)$ that has a Fourier transform equal the the right-hand-side of Eq. 22-15—or, equivalently, operating with the inverse Fourier transform on the right-hand-side of Eq. 22-15.

MATHEMATICA[®] Example: (notebook) Lecture-22

Operator Calculus and the Solution to the Damped-Forces Harmonic Oscillator Model

MATHEMATICA[®] does have built-in functions to take Fourier (and other kinds of) integral transforms. However, as will be seen below, using operational calculus to solve ODEs is not necessarily simple in MATHEMATICA[®]. Nevertheless, it may be instructive to force it—if only as an example of using the good tool for the wrong purpose.

Rules for Linear Operators

☹ *Operators to Functionals*

Equally powerful is the concept of a *functional* which takes a function as an argument and returns a value. For example $\mathcal{S}[y(x)]$, defined below, operates on a function $y(x)$ and returns its surface of revolution's area for $0 < x < L$:

$$\mathcal{S}[y(x)] = 2\pi \int_0^L y \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx \quad (22-16)$$

This is the functional to be minimized for the question, “Of all surfaces of revolution that span from $y(x=0)$ to $y(x=L)$, which is the $y(x)$ that has the smallest surface area?”

This idea of finding “which function maximizes or minimizes something” can be very powerful and practical.

Suppose you are asked to run an “up-hill” race from some starting point $(x = 0, y = 0)$ to some ending point $(x = 1, y = 1)$ and there is a ridge $h(x, y) = x^2$. What is the most efficient running route $y(x)$?¹³

A reasonable model for running speed as a function of climbing-angle α is

$$v(s) = \cos(\alpha(s)) \quad (22-17)$$

where s is the arclength along the path. The maximum speed occurs on flat ground $\alpha = 0$ and running speed monotonically falls to zero as $\alpha \rightarrow \pi/2$. To calculate the time required to traverse *any* path $y(x)$ with endpoints $y(0) = 0$ and $y(1) = 1$,

¹³ An amusing variation on this problem would be to find the path that the path that a winning downhill skier should traverse.

$$\begin{aligned}\frac{ds}{dt} = v(s) = \cos(\alpha(s)) &= \frac{ds}{\sqrt{ds^2 + dh^2}} = \frac{1}{\sqrt{1 + \frac{dh^2}{ds^2}}} = \frac{1}{\sqrt{1 + \frac{dh^2}{dx^2 + dy^2}}} \\ dt = \frac{ds}{v(s)} &= \frac{\sqrt{dx^2 + dy^2}}{\cos(\alpha(s))} = \sqrt{dx^2 + dy^2 + dh^2} = \sqrt{1 + \frac{dy^2}{dx^2} + \frac{dh^2}{dx^2}} dx\end{aligned}\quad (22-18)$$

So, with the hill $h(x) = x^2$, the time as a functional of the path is:

$$\mathcal{T}[y(x)] = \int_0^1 \sqrt{1 + \frac{dy^2}{dx^2} + 4x^2} dx \quad (22-19)$$

MATHEMATICA[®] Example: (notebook) Lecture-22

Functionals: Introduction to Variational Calculus by Variation of Parameters

1. Instead of trying to find the function $y(x)$ (if such a function exists) that minimizes the function in Eq. 22-19, consider the polynomial $y(x) = a + bx + cx^2$ as an “approximating function” and then find the parameters a , b , and c , that minimize the functional.
2. Ensure that the cubic equation satisfies the boundary conditions and thereby fix two of the three free parameters
3. By integrating $y(x)$ in Eq. 22-19, the functional equation is transformed to a function of the remaining free variable. (It is much easier in MATHEMATICA[®] to integrate without limits in Eq. 22-19 and then evaluate the limits in a separate step.)
4. Find the parameter that minimizes the integral.
5. Visualize the quickest path.

There is a powerful and beautiful mathematical method for finding the extremal functions of functionals which is called *Calculus of Variations*.

By using the calculus of variations, the optimal path $y(x)$ for Eq. 22-19 can be determined:

$$y(x) = \frac{2x\sqrt{1+4x^2} + \sinh^{-1}(2x)}{2\sqrt{5} + \sinh^{-1}(2)} \quad (22-20)$$

The approximation determined in the MATHEMATICA[®] example above is pretty good.

Harmonic Oscillators

Methods for finding general solution to the linear inhomogeneous second-order ODE

$$a \frac{d^2 y(t)}{dt^2} + b \frac{dy(t)}{dt} + cy(t) = F(t) \quad (22-21)$$

have been developed and worked out in MATHEMATICA[®] examples.

Eq. 22-21 arises frequently in physical models, among the most common are:

$$\begin{aligned} \text{Electrical circuits:} \quad & L \frac{d^2 I(t)}{dt^2} + \rho l_o \frac{dI(t)}{dt} + \frac{1}{C} I(t) = V(t) \\ \text{Mechanical oscillators:} \quad & M \frac{d^2 y(t)}{dt^2} + \eta l_o \frac{dy(t)}{dt} + K_s y(t) = F_{app}(t) \end{aligned} \quad (22-22)$$

where:

	Mechanical	Electrical
Second Order	Mass M : Physical measure of the ratio of momentum field to velocity	Inductance L : Physical measure of the ratio of stored magnetic field to current
First Order	Drag Coefficient $c = \eta l_o$ (η is viscosity l_o is a unit displacement): Physical measure of the ratio environmental resisting forces to velocity—or proportionality constant for energy dissipation with square of velocity	Resistance $R = \rho l_o$ (ρ is resistance per unit material length l_o is a unit length): Physical measure of the ratio of voltage drop to current—or proportionality constant for power dissipated with square of the current.
Zeroth Order	Spring Constant K_s : Physical measure of the ratio environmental force developed to displacement—or proportionality constant for energy stored with square of displacement	Inverse Capacitance $1/C$: Physical measure of the ratio of voltage storage rate to current—or proportionality constant for energy storage rate dissipated with square of the current.
Forcing Term	Applied Voltage $V(t)$: Voltage applied to circuit as a function of time.	Applied Force $F(t)$: Force applied to oscillator as a function of time.

For the homogeneous equations (i.e. no applied forces or voltages) the solutions for physically allowable values of the coefficients can either be oscillatory, oscillatory with damped amplitudes, or, completely damped with no oscillations. (See Figure 21-1). The homogeneous equations are sometimes called *autonomous* equations—or *autonomous systems*.

☹ Simple Undamped Harmonic Oscillator

The simplest version of a homogeneous Eq. 22-21 with no damping coefficient ($b = 0$, $R = 0$, or $\eta = 0$) appears in a remarkably wide variety of physical models. This simplest physical model is a simple harmonic oscillator—composed of a mass accelerating with a linear

spring restoring force:

$$\text{Inertial Force} = \text{Restoring Force}$$

$$M \text{Acceleration} = \text{Spring Force}$$

$$M \frac{d^2 y(t)}{dt^2} = -K_s y(t) \quad (22-23)$$

$$M \frac{d^2 y(t)}{dt^2} + K_s y(t) = 0$$

Here y is the displacement from the equilibrium position—i.e., the position where the force, $F = -dU/dx = 0$. Eq. 22-23 has solutions that oscillate in time with frequency ω :

$$\begin{aligned} y(t) &= A \cos \omega t + B \sin \omega t \\ y(t) &= C \sin(\omega t + \phi) \end{aligned} \quad (22-24)$$

where $\omega = \sqrt{K_s/M}$ is the natural frequency of oscillation, A and B are integration constants written as amplitudes; or, C and ϕ are integration constants written as an amplitude and a phase shift.

The simple harmonic oscillator has an *invariant*, for the case of mass-spring system the invariant is the total energy:

$$\begin{aligned} \text{Kinetic Energy} + \text{Potential Energy} &= \\ \frac{M}{2} v^2 + \frac{K_s}{2} y^2 &= \\ \frac{M}{2} \frac{dy^2}{dt} + \frac{K_s}{2} y^2 &= \\ A^2 \omega^2 \frac{M}{2} \cos^2(\omega t + \phi) + A^2 \frac{K_s}{2} \sin^2(\omega t + \phi) &= \\ A^2 \left(\omega^2 \frac{M}{2} \cos^2(\omega t + \phi) + \frac{M \omega^2}{2} \sin^2(\omega t + \phi) \right) &= \\ A^2 M \omega^2 &= \text{constant} \end{aligned} \quad (22-25)$$

There are a remarkable number of physical systems that can be reduced to a simple harmonic oscillator (i.e., the model can be reduced to Eq. 22-23). Each such system has an analog to a mass, to a spring constant, and thus to a natural frequency. Furthermore, every such system will have an invariant that is an analog to the total energy—an in many cases the invariant will, in fact, be the total energy.

The advantage of reducing a physical model to a harmonic oscillator is that *all of the physics follows from the simple harmonic oscillator*.

Here are a few examples of systems that can be reduced to simple harmonic oscillators:

Pendulum By equating the rate of change of angular momentum equal to the torque, the equation for pendulum motion can be derived:

$$MR^2 \frac{d^2\theta}{dt^2} + MgR \sin \theta = 0 \quad (22-26)$$

for small-amplitude pendulum oscillations, $\sin(\theta) \approx \theta$, the equation is the same as a simple harmonic oscillator.

It is instructive to consider the invariant for the non-linear equation. Because

$$\frac{d^2\theta}{dt^2} = \frac{d\theta}{dt} \left(\frac{d\frac{d\theta}{dt}}{d\theta} \right) \quad (22-27)$$

Eq. 22-26 can be written as:

$$MR^2 \frac{d\theta}{dt} \left(\frac{d\frac{d\theta}{dt}}{d\theta} \right) + MgR \sin(\theta) = 0 \quad (22-28)$$

$$\frac{d}{d\theta} \left[\frac{MR^2}{2} \left(\frac{d\theta}{dt} \right)^2 - MgR \cos(\theta) \right] = 0 \quad (22-29)$$

which can be integrated with respect to θ :

$$\frac{MR^2}{2} \left(\frac{d\theta}{dt} \right)^2 - MgR \cos(\theta) = \text{constant} \quad (22-30)$$

This equation will be used as a level-set equation to visualize pendulum motion.

Buoyant Object Consider a buoyant object that is slightly displaced from its equilibrium floating position. The force (downwards) due to gravity of the buoy is $\rho_{\text{buoy}} g V_{\text{buoy}}$. The force (upwards) according to Archimedes is $\rho_{\text{water}} g V_{\text{sub}}$ where V_{sub} is the volume

of the buoy that is submerged. The equilibrium position must satisfy $V_{sub-eq}/V_{buoy} = \rho_{buoy}/\rho_{water}$.

If the buoy is slightly perturbed at equilibrium by an amount δx the force is:

$$\begin{aligned} F &= \rho_{water}g(V_{sub-eq} + \delta x A_o) - \rho_{buoy}gV_{buoy} \\ F &= \rho_{water}g\delta x A_o \end{aligned} \quad (22-31)$$

where A_o is the cross-sectional area at the equilibrium position. Newton's equation of motion for the buoy is:

$$M_{buoy} \frac{d^2 y}{dt^2} - \rho_{water}gA_o y = 0 \quad (22-32)$$

so the characteristic frequency of the buoy is $\omega = \sqrt{\rho_{water}gA_o/M_{buoy}}$.

Single Electron Wave-function The one-dimensional Schrödinger equation is:

$$\frac{d^2 \psi}{dx^2} + \frac{2m}{\hbar^2} (E - U(x)) \psi = 0 \quad (22-33)$$

where $U(x)$ is the potential energy at a position x . If $U(x)$ is constant as in a free electron in a box, then the one-dimensional wave equation reduces to a simple harmonic oscillator.

In summation, just about any system that oscillates about an equilibrium state can be reduced to a harmonic oscillator.
