Lecture 21: Higher-Order Ordinary Differential Equations

Reading: Kreyszig Sections: 2.1, 2.2 (pages45–52, 53–58)

## Higher-Order Equations: Background

For first-order ordinary differential equations (ODEs), F(y'(x), y(x), x), one value  $y(x_o)$  was needed to specify a particular solution. Recall the example in Lecture 19 of a first-order differencing scheme: at each iteration the function grew proportionally to its current size. In the limit of very small forward differences, the scheme converged to exponential growth.

Now consider a situation in which function's current rate of growth increases proportionally to two terms: its current rate of growth and its size.

Change in Value's Rate of Change +  $\alpha$  (the Value) +  $\beta$  (Value's Rate of Change) = 0

To calculate a forward differencing scheme for this case, let  $\Delta$  be the forward-differencing increment.

 $\left(\frac{\frac{F_{i+2}-F_{i+1}}{\Delta}-\frac{F_{i+1}-F_i}{\Delta}}{\Delta}\right)+\alpha F_i+\beta\left(\frac{F_{i+1}-F_i}{\Delta}\right)=0$ 

and then solve for the "next increment"  $F_{i+2}$  if  $F_{i+1}$  and  $F_i$  are known.

This indicates that, for second-order equations, two independent values are needed to generate the 'solution trajectory.'

A Second-Order Forward Differencing Example

A second order differencing formula is developed for second-order equations. The current value of the right-hand side is used, and therefore this is an explicit method.

- ChangePer $\Delta$ [ $F_{-}$ ,  $i_{-}$ ,  $\Delta_{-}$ ] :=  $(F[i+1] - F[i]) / \Delta$ **ChangeofChangeper**∆[  $F_{-}, i_{-}, \Delta_{-}] :=$ Simplify[(ChangePer∆[ F, i + 1,  $\Delta$ ] / $\Delta$  -ChangePer $\Delta$ [*F*, *i*,  $\Delta$ ])] DifferenceRelation = **ChangeofChangeper**∆[  $F, i, \Delta$ ] ==  $-\beta$  ChangePer $\Delta$ [F, i,  $\Delta$ ] - $\alpha F[i]$ ForDiffSol = Collect[ Solve[DifferenceRelation,  $F[i+2]], \Delta]$ Replace to find the form of the solution ForDiffSolV2 = ForDiffSol /.  $i \rightarrow j - 2$  $\left\{ \left\{ F\left[ j\right] \right\} \right\}$  $-\alpha \bigtriangleup^2 F[-2+j] + F[-1+j] +$  $\triangle$  (-F[-2 + j] +  $\beta$  F[-2 + j] +  $F[-1+j] - \beta F[-1+j])$
- 1:  $Changeper\Delta$  is an example of a first-order finite difference approximation to the first derivative.
- 2: ChangeofChangeper $\Delta$  is the second order difference operation, it is obtained by applying the firstorder difference operator twice. Note that two sequential values appear and that the differencing operator is proportional to  $1/\Delta^2$ . This is a general feature of high-order difference operators with higher difference operations goes, the number of surrounding points required to evaluate the difference gets larger and larger (e.g., for the second order difference, function values are needed at three different *i* compared to two different *i* for the first-order case.

pdf (evaluated, b&w)

- 3: For a particular case of  $d^2y/dx^2 = -\alpha dy/dx \beta y$ , the two difference operators replace the derivatives and a difference relation can be derived as a function of parameters  $\alpha$  and  $\beta$ . We assign the equation representing the difference relation to DifferenceRelation.
- 4: The difference operator is derived by solving the difference relation for  $F_{i+2}$ —it will depend on the immediate last value  $F_{i+1}$  and that value's antecedent  $F_i$ . Therefore, any value—including the first one calculated—requires two values to be specified.
- 5: Typically, the current *j*-value is expressed in terms of the (j-1) and (j-2)-values. This form is generated by the replacement  $i \rightarrow j-2$ .

### Linear Differential Equations; Superposition in the Homogeneous Case

A linear differential equation is one for which the function and its derivatives are each linear—that is they appear in distinct terms and only to the first power. In the case of a homogeneous linear differential equation, the solutions are *superposable*. In other words, sums of solutions and their multiples are also solutions.

Therefore, a linear heterogeneous ordinary differential equation can be written as a product of general functions of the dependent variable and the derivatives for the *n*-order linear case:

$$0 = f_0(x) + f_1(x)\frac{dy}{dx} + f_2(x)\frac{d^2y}{dx^2} + \dots + f_n(x)\frac{d^ny}{dx^n}$$

$$= (f_0(x), f_1(x), f_2(x), \dots, f_n(x)) \cdot \left(1, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n}\right)$$

$$= \vec{f}(x) \cdot \vec{D_n y}$$
(21-1)

The homogeneous  $n^{th}$ -order linear ordinary differential equation is defined by  $f_0(x) = 0$  in Eq. 21-1:

$$0 = f_1(x)\frac{dy}{dx} + f_2(x)\frac{d^2y}{dx^2} + \dots + f_n(x)\frac{d^ny}{dx^n} = (0, f_1(x), f_2(x), \dots, f_n(x)) \cdot \left(1, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n}\right)$$
(21-2)  
=  $\vec{f_{hom}}(x) \cdot \vec{D_n y}$ 

Close

Equation 21-1 can always be multiplied by  $1/f_n(x)$  to generate the general form:

$$0 = F_0(x) + F_1(x)\frac{dy}{dx} + F_2(x)\frac{d^2y}{dx^2} + \dots + \frac{d^ny}{dx^n}$$
  
=  $(F_0(x), F_1(x), F_2(x), \dots, 1)) \cdot (1, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n})$   
=  $\vec{F}(x) \cdot \vec{D_n y}$   
(21-3) Quit  
(21-3)

For the second-order linear ODE, the heterogeneous form can always be written as:

$$\frac{d^2y}{dx^2} + p(x)\frac{dy}{dx} + q(x)y = r(x)$$

and the homogeneous second-order linear ODE is:

$$\frac{d^2y}{dx^2} + p(x)\frac{dy}{dx} + q(x)y = 0$$
(21-5)

Basis Solutions for the homogeneous second-order linear ODE

Because two values must be specified for each solution to a second order equation—the solution can be broken into two basic parts, each deriving from a different constant. These two independent solutions form a *basis pair* for any other solution to the homogeneous second-order linear ODE that derives from any other pair of specified values.

The idea is the following: suppose the solution to Eq. 21-5 is found the particular case of specified parameters  $y(x = x_0) = A_0$ and  $y(x = x_1) = A_1$ , the solution  $y(x; A_0, A_1)$  can be written as the sum of solutions to two *other problems*.

$$y(x; A_0, A_1) = y(x, A_0, 0) + y(x, 0, A_1) = y_1(x) + y_2(x)$$
 [21-6] Full Screen

where

 $y(x_0, A_0, 0) = A_0 \quad \text{and} \quad y(x_1, A_0, 0) = 0$   $y(x_0, 0, A_1) = 0 \quad \text{and} \quad y(x_1, 0, A_1) = A_1$ (21-7)
(21-7)

from these two solutions, any others can be generated.

The two arbitrary integration constants can be included in the definition of the general solution:

$$y(x) = C_1 y_1(x) + C_1 y_2(x)$$
  
=  $(C_1, C_2) \cdot (y_1, y_2)$ 

(21-8)

(21-4)

## Second Order ODEs with Constant Coefficients

The most simple case—but one that results from models of many physical phenomena—is that functions in the homogeneous second-order linear ODE (Eq. 21-5) are constants:

$$a\frac{d^2y}{dx^2} + b\frac{dy}{dx} + cy = 0$$
(21-9)

If two independent solutions can be obtained, then any solution can be formed from this basis pair.

Surmising solutions seems a sensible strategy, certainly for shrewd solution seekers. Suppose the solution is of the form  $y(x) = \exp(\lambda x)$  and put it into Eq. 21-9:

$$(a\lambda^2 + b\lambda + c)e^{\lambda x} = 0 \tag{21-10}$$

which has solutions when and only when the quadratic equation  $a\lambda^2 + \lambda x + c = 0$  has solutions for  $\lambda$ .

Because two solutions are needed and because the quadratic equation yields two solutions:

$-b+\sqrt{b^2-4ac}$		
$\lambda_{+} = \frac{-b + \sqrt{b} - 4ac}{2c}$		Full Screen
$\frac{2a}{\sqrt{12}}$	(21-11)	
$\lambda_{-} = \frac{-b - \sqrt{b^2 - 4ac}}{c}$		
2a		

or by removing the redundant coefficient by diving through by a:

 $\lambda_{+} = \frac{-\beta}{2} + \sqrt{\left(\frac{\beta}{2}\right)^{2} - \gamma}$  $\lambda_{-} = \frac{-\beta}{2} - \sqrt{\left(\frac{\beta}{2}\right)^{2} - \gamma}$ 

where  $\beta \equiv b/a$  and  $\gamma \equiv c/a$ .

Quit

Close

(21-12)

3.016 Home

Therefore, any solution to Eq. 21-9 can be written as

$$y(x) = C_+ e^{\lambda_+ x} + C_- e^{\lambda_- x}$$

This solution recreated with a slightly different method in the following MATHEMATICAR example.

 Deriving the Solutions to the Homogeneous Linear Second Order ODE with Constant Coefficients

 Even though MATHEMATICA® is able to determine solutions to linear second-order ODEs with constant coefficients directly, it is still

 instructive to use MATHEMATICA® to derive these solutions.

<pre>TheODE[function_, var_] := D[function[var],</pre>	
<pre>{var, 2}] +</pre>	1
γ function[var]	
TheODE[y, x]	2
Guess a solution and substitute it into th hand side of the ODE:	e left
TheGuess $[x_{\perp}] := \operatorname{Exp}[\lambda x]$	3
TheODE[TheGuess, x]	4
This will be a solution when the resulting quadratic expression in $\lambda$ is equal to 0:	1
λSolution = Solve[ TheODE[TheGuess, x] == 0, λ]	5
{λMinus, λPlus} =	6
$\lambda /. \lambda$ Solution	1
GenSol[x_] :=	
$C[LPlus] Exp[\lambda Plus x] +$	7
$C[LMinus] Exp[\lambda Minus x]$	
TheODE[GenSol, z]	8
Simplify[TheODE[GenSol, z]]	9

- **1–2:** The ODE represents the left-hand side of any second-order ODE with constant coefficients—it is the differential representation of the second-order differencing method that was developed above. The ODE an argument for the name of the function (i.e., y) and the dependent variable (i.e., x in y(x)).
- 3: This will serve as a 'guess' of a solution—if we can find  $\lambda(s)$  that satisfy the ODE, then the solution(s) are determined.
- 4: The guess is inserted as the first argument to *TheODE*. The property of the exponential function,  $de^{\alpha x}/dx = d(guess)/dx = \alpha e^{\alpha x} = \alpha guess$  will permit factoring of the 'guessed' solution.
- 5: Using Solve with the guess inserted into *TheODE* will determine solution conditions on  $\lambda$ —this will be a quadratic equation in  $\lambda$ . The quadratic equation's solution ensures that, if the solution is complex, the two  $\lambda$  are complex conjugates.
- 6: By extraction the solution from the rules returned from Solve, assignments can be made to the two possible  $\lambda$ .
- 7: This is the form of the general solution in terms of two arbitrary constants.
- 8: This should show that the general solution always satisfies the ODE.

 Characterizing the Solution Behavior
 for the Second-Order ODE with Constant Coefficients
 html (evaluated)

Because the fundamental solution depend on only two parameters  $\beta$  and  $\gamma$ , the behavior (i.e., whether  $\Re \lambda \stackrel{?}{<} 0$  and  $\Im \lambda \stackrel{?}{=} 0$ ) of all solutions can be visualized in the  $\gamma$ - $\beta$  plane.

-1.0 -0.5 0.0 0.5 1.0

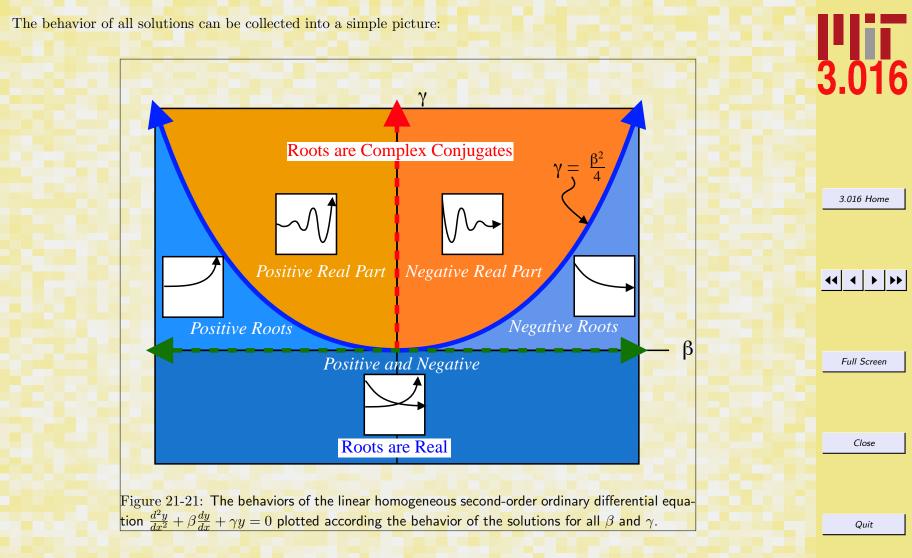

- 1: Reduce is a function for determining the conditions on parameters (here  $\beta$  and  $\gamma$  assumed to be real numbers) such that an expression satisfies particular constraints. The results from Reduce will be used to build up a graphical representation of solution behavior by incremental steps.
- A: (Algorithm suppressed in class-notes) RegionPlot is used in conjunction with the results produced by Reduce to illustrate the domains where the  $\lambda$  are complex and real. The regions are annotated and saved as a graphic to be concatenated below. This will create a plot that distinguishes two regions in the  $\gamma$ - $\beta$  plane: above  $\gamma = \beta^2/4$ , the  $\lambda$  are real; below, the  $\lambda$  are complex and oscillatory solutions appear (because  $\exp(r + i\theta) = \exp(r)(\cos(\theta) + i\sin(\theta))$ ).
- **B**: The sign of the real part of the complex  $\lambda$  changes at  $\beta = 0$ . Here a graphic and its notation are created.
- C: Using Reduce and RegionPlot in a manner that parallels A, domains for the  $\lambda$  having two real roots with the same sign are plotted and annotated.
- **D**: Finally, the domain when the  $\lambda$  are real with opposite sign are illustrated.
- 2: Concatenating all the graphical objects together with Show produces the image that was used to construct Fig. 21-21.

The case that separates the complex solutions from the real solutions,  $\gamma = (\beta/2)^2$  must be treated separately, for the case  $\gamma = (\beta/2)^2$  it can be shown that  $y(x) = \exp(\beta x/2)$  and  $y(x) = x \exp(\beta x/2)$  form an independent basis pair (see Kreyszig ©W.

©W. Craig Carter

*AEM*, p. 74).

#### **Boundary Value Problems**

It has been shown that all solutions to  $\frac{d^2y}{dx^2} + \beta \frac{dy}{dx} + \gamma y = 0$  can be determined from a linear combination of the basis solution. Disregard for a moment whether the solution is complex or real, and ignoring the special case  $\gamma = (\beta/2)^2$ . The solution to any problem is given by

$$y(x) = C_{+}e^{\lambda_{+}x} + C_{-}e^{\lambda_{-}x}$$
(21-14)

How is a solution found for a particular problem? Recall that *two values* must be specified to get a solution—these two values are just enough so that the two constants  $C_+$  and  $C_-$  can be obtained.

In many physical problems, these two conditions appear at the boundary of the domain. A typical problem is posed like this:

Solve

$$m\frac{d^2y(x)}{dx^2} + \nu\frac{dy(x)}{dx} + ky(x) = 0 \qquad \text{on } 0 < x < L \qquad (21-15)$$

subject to the boundary conditions

$$y(x=0) = 0 \qquad \text{and} \qquad y(x=L) = 1$$

or, solve

$$m\frac{d^2y(x)}{dx^2} + \nu\frac{dy(x)}{dx} + ky(x) = 0 \qquad \text{on } 0 < x < \infty$$

subject to the boundary conditions

y(x = 0) = 1 and y'(x = L) = 0

When the value of the function is specified at a point, these are called *Dirichlet* conditions; when the derivative is specified, the boundary condition is called a *Neumann* condition. It is possible have boundary conditions that are mixtures of Dirichlet and Neumann.

GenSol[x] /. SolutionTwo]

## Fourth Order ODEs, Elastic Beams

Another linear ODE that has important applications in materials science is that for the deflection of a beam. The beam deflection y(x) is a linear fourth-order ODE:

$$\frac{d^2}{dx^2} \left( EI \frac{d^2 y(x)}{dx^2} \right) = w(x) \tag{21-1}$$

where w(x) is the load density (force per unit length of beam), E is Young's modulus of elasticity for the beam, and I is the moment of inertia of the cross section of the beam:

$$I = \int_{A_{\times -sect}} y^2 dA \tag{21-18}$$

is the second-moment of the distribution of heights across the area.

If the moment of inertia and the Young's modulus do not depend on the position in the beam (the case for a uniform beam of homogeneous material), then the beam equation becomes:

$$EI\frac{d^4y(x)}{dx^4} = w(x)$$
(21-19)

The homogeneous solution can be obtained by inspection—it is a general cubic equation  $y_{homog}(x) = C_0 + C_1 x + C_2 x^2 + C_3 x^3$ which has the four constants that are expected from a fourth-order ODE.

The particular solution can be obtained by integrating w(x) four times—if the constants of integration are included then the particular solution naturally contains the homogeneous solution.

The load density can be discontinuous or it can contain Dirac-delta functions  $F_o\delta(x-x_o)$  representing a point load  $F_o$  applied at  $x = x_o$ .

It remains to determine the constants from boundary conditions. The boundary conditions can be determined because each derivative of y(x) has a specific meaning as illustrated in Fig. 21-22.

## A Gratuitous Animations of Deflections of a Diving Board

A diving board can be approximated as a beam of uniform stiffness which is cantilevered at one end, and has an adjustable pin near its center. We work out a solution and visualization for a diver walking out on a diving board with the pin fixed at the center.

We wish to simulate the deflection of a diving board as a diver walks toward the end. A diving board may be modeled as beam with constant cross-section. The boundary conditions are that the board is clamped at the beginning; has a pivot located somewhere near the center; and the "diving" end. For "competitive" diving boards, the pivot point is adjustable. Here we fix the pivot at x=1/2.

This next function is a silly little graphic for the walking diver.

A: (Solution and Algorithm Suppressed) We start by defining a set of graphics that take a single argument to represent the diver, the argument is designed to make the diver appear to be walking. The solution to this deflection of the diving board is not trivial. The diver is modeled as a point load. The board is modeled as a piecewise solution for two beams that share a common boundary condition. We will need to match boundary conditions at the pin. The method is to find a solution in terms of an arbitrary coefficient, and then solve for the instance of that coefficient that makes the board deflection continuous.

pdf (evaluated, b&w)

If the diver is located between the cantilever and the pin, then the deflection in this region is determined with simple clamp and pin boundary conditions and the DiracDelta function for the distributed load. From this solution, the slope at the mid-point is calculated and this value is used as one of the boundary condition between the pin and the free-end.

If the diver is located between the pin and the free-end, the the slope at the pin is an undermined constant first in this region and then in the region between the cantilever and the pin. Solve is used to match the slope at the pin, and that solution is applied to the previously obtained solutions (i.e., the solutions from DSolve.

Piecewise is used in the definition of the solution-function that is returned. Manipulate is used to specify the position of the diver. 3.016 Home
