Eigenvalues and Eigenvectors of a Matrix

The conditions for which general linear equation
\[ A\vec{x} = \vec{b} \] (9-1)
has solutions for a given matrix \( A \), fixed vector \( \vec{b} \), and unknown vector \( \vec{x} \) have been determined.

The operation of a matrix on a vector—whether as a physical process, or as a geometric transformation, or just a general linear equation—has also been discussed.

Eigenvalues and eigenvectors are among the most important mathematical concepts with a very large number of applications in physics and engineering.

An eigenvalue problem (associated with a matrix \( A \)) relates the operation of a matrix multiplication on a particular vector \( \vec{x} \) to its multiplication by a particular scalar \( \lambda \).

\[ A\vec{x} = \lambda\vec{x} \] (9-2)

This equation indicates that the matrix operation can be replaced—or is equivalent to—a stretching or contraction of the vector: “\( A \) has some vector \( \vec{x} \) for which its multiplication is simply a scalar multiplication operation by \( \lambda \),” \( \vec{x} \) is an eigenvector of \( A \) and \( \lambda \) is \( \vec{x} \)'s associated eigenvalue.

The condition that Eq. 9-2 has solutions is that its associated homogeneous equation:
\[ (A - \lambda I)\vec{x} = \vec{0} \] (9-3)
has a zero determinant:
\[ \det(A - \lambda I) = 0 \] (9-4)

Eq. 9-4 is a polynomial equation in \( \lambda \) (the power of the polynomial is the same as the size of the square matrix).

The eigenvalue-eigenvector system in Eq. 9-2 is solved by the following process:

1. Solve the characteristic equation (Eq. 9-4) for each of its roots \( \lambda_i \).

2. Each root \( \lambda_i \) is used as an eigenvalue in Eq. 9-2 which is solved for its associated eigenvector \( \vec{x}_i \).
Calculating Matrix Eigenvalues and Eigenvectors

The symbolic computation of eigenvalues and eigenvectors is demonstrated for simple $2 \times 2$ matrices. This example is illustrative—more interesting uses would be for larger matrices. In this example, a “cheat” is employed so that a matrix with “interesting” eigenvalues and eigenvectors is used as computation fodder.

1: A “typical” $2 \times 2$ matrix `mymatrix` is defined for the calculations that follow. We will calculate its eigenvalues directly and with a built-in function.

2: Its eigenvalues can be obtained by by using `Solve` for the characteristic equation Eq. 9-4 in terms of $\lambda$.

3: And, its eigenvectors could be obtained by putting each eigenvalue back into Eq. 9-2 and then solving $\vec{x}$ for each unique $\lambda$. However, this tedious procedure can also be performed with `Eigenvectors`

4: Here, a matrix of eigenvectors is defined with named rows `evec1` and `evec2`.

5: `Eigensystem` generates the same results as `Eigenvectors` and `Eigenvalues` in one step.
The matrix operation on a vector that returns a vector that is in the same direction is an eigensystem. A physical system that is associated can be interpreted in many different ways:

**geometrically** The vectors \( \vec{x} \) in Eq. 9-2 are the ones that are unchanged by the linear transformation on the vector.

**iteratively** The vector \( \vec{x} \) that is processed (either forward in time or iteratively) by \( A \) increases (or decreases if \( \lambda < 1 \)) along its direction.

In fact, the eigensystem can be (and will be many times when they are) generalized to other interpretations and generalized beyond linear matrix systems.

Here are some examples where eigenvalues arise. These examples generalize beyond matrix eigenvalues.

- As an analogy that will become real later, consider the “harmonic oscillator” equation for a mass, \( m \), vibrating with a spring-force, \( k \), this is simply Newton’s equation:

\[
m \frac{d^2 x}{dt^2} = k x
\]  

(9-5)

If we treat the second derivative as some linear operator, \( \mathcal{L}_{\text{spring}} \) on the position \( x \), then this looks like an eigenvalue equation:

\[
\mathcal{L}_{\text{spring}} x = \frac{k}{m} x
\]  

(9-6)

- Letting the positions \( x_i \) form a vector \( \vec{x} \) of a bunch of atoms of mass \( m_i \), the harmonic oscillator can be generalized to a bunch of atoms that are interacting as if they were attached to each other by springs:

\[
m_i \frac{d^2 x_i}{dt^2} = \sum \limits_{i \text{'s near neighbors } j} k_{ij} (x_i - x_j)
\]  

(9-7)
For each position $i$, the $j$-terms can be added to each side, leaving an operator that looks like:

$$\mathcal{L}_{\text{lattice}} = \begin{pmatrix} m_1 \frac{d^2}{dt^2} & -k_{12} & 0 & -k_{14} & \ldots & 0 \\ -k_{21} & m_2 \frac{d^2}{dt^2} & -k_{23} & 0 & \ldots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & m_i \frac{d^2}{dt^2} & \ddots & \vdots \\ 0 & 0 & \ldots & m_{N-1} \frac{d^2}{dt^2} & -k_{N-1}N \\ 0 & 0 & \ldots & -k_{N}N & m_N \frac{d^2}{dt^2} \end{pmatrix}$$

(9-8)

The operator $\mathcal{L}_{\text{lattice}}$ has diagonal entries that have the spring (second-derivative) operator and one off-diagonal entry for each other atom that interacts with the atom associated with row $i$. The system of atoms can be written as:

$$k^{-1} \mathcal{L}_{\text{lattice}} \mathbf{x} = \mathbf{x}$$

(9-9)

which is another eigenvalue equation and solutions are constrained to have unit eigenvalues—these are the ‘normal modes.’

- To make the above example more concrete, consider a system of three masses connected by springs.

![Figure 9-5: Four masses connected by three springs](image)

The equations of motion become:

$$\begin{pmatrix} m_1 \frac{d^2}{dt^2} & -k_{12} & -k_{13} & -k_{14} \\ -k_{12} & m_2 \frac{d^2}{dt^2} & 0 & 0 \\ -k_{13} & 0 & m_2 \frac{d^2}{dt^2} & 0 \\ -k_{14} & 0 & 0 & m_2 \frac{d^2}{dt^2} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} k_{12} + k_{13} + k_{14} & 0 & 0 & 0 \\ 0 & k_{12} & 0 & 0 \\ 0 & 0 & k_{13} & 0 \\ 0 & 0 & 0 & k_{14} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix}$$

(9-10)
which can be written as
\[ \mathcal{L}_{4\times4} \vec{x} = k \vec{x} \]  \hspace{1cm} (9-11)

or
\[ k^{-1} \mathcal{L}_{4\times4} \vec{x} = \vec{x} \]  \hspace{1cm} (9-12)

As will be discussed later, this system of equations can be “diagonalized” so that it becomes four independent equations. Diagonalization depends on finding the eigensystem for the operator.

- The one-dimensional Shrödinger wave equation is:
\[ -\frac{\hbar}{2m} \frac{d^2 \psi(x)}{dx^2} + U(x)\psi(x) = E\psi(x) \]  \hspace{1cm} (9-13)

where the second derivative represents the kinetic energy and \( U(x) \) is the spatial-dependent potential energy. The “Hamiltonian Operator” \( \mathcal{H} = -\frac{\hbar}{2m} \frac{d^2}{dx^2} + U(x) \), operates on the wavefunction \( \psi(x) \) and returns the wavefunction's total energy multiplied by the wave-vector;
\[ \mathcal{H}\psi(x) = E\psi(x) \]  \hspace{1cm} (9-14)

This is another important eigenvalue equation (and concept!)

**Symmetric, Skew-Symmetric, Orthogonal Matrices**

Three types of matrices occur repeatedly in physical models and applications. They can be placed into three categories according to the conditions that are associated with their eigenvalues:

**All real eigenvalues** Symmetric matrices—those that have a “mirror-plane” along the northwest–southeast diagonal \( A = A^T \)—must have all real eigenvalues.

Hermitian matrices—the complex analogs of symmetric matrices—in which the reflection across the diagonal is combined with a complex conjugate operation \( a_{ij} = \bar{a}_{ji} \), must also have all real eigenvalues.

**All imaginary eigenvalues** Skew-symmetric (diagonal mirror symmetry combined with a minus) matrices \( -A = A^T \) must have all complex eigenvalues.

Skew-Hermitian matrices—the complex analogs of skew-symmetric matrices \( a_{ij} = -\bar{a}_{ji} \)—have all imaginary eigenvalues.

**Unitary Matrices: unit determinant** Real matrices that satisfy \( A^T = A^{-1} \) have the property that product of all the eigenvalues is \( \pm 1 \). These are called orthogonal matrices and they have orthonormal rows. Their determinants are also \( \pm 1 \).

This is generalized by complex matrices that satisfy \( \bar{A}^T = A^{-1} \). These are called unitary matrices and their (complex) determinants have magnitude 1. Orthogonal matrices, \( A \), have the important physical property that they preserve the inner product: \( \vec{x} \cdot \vec{y} = (A\vec{x}) \cdot (A\vec{y}) \). When the orthogonal matrix is a rotation, the interpretation is that the vectors maintain their relationship to each other if they are both rotated.
Orthogonal Transformations

Multiplication of a vector by an orthogonal matrix is equivalent to an orthogonal geometric transformation on that vector.

For orthogonal transformation, the inner product between any two vectors is *invariant*. That is, the inner product of two vectors is always the same as the inner product of their images under an orthogonal transformation. Geometrically, the projection (or the angular relationship) is unchanged. This is characteristic of a rotation, or a reflection, or an inversion.

Rotations, reflections, and inversions are orthogonal transformations. The product of orthogonal matrices is also an orthogonal matrix.
Here we demonstrate that a matrix, composed of columns of constructed eigenvectors of a matrix, can be used to diagonalize a matrix, and the resulting diagonal entries are the matrix eigenvalues.

1: The matrix simtrans is constructed by assigning rows defined by the eigenvectors from the previous example and then transposing (Transpose) so that the eigenvectors are the columns.

2: The original matrix is left-multiplied by the inverse of simtrans and right-multiplied by simtrans; the result will be a diagonal matrix with the original matrix’s eigenvalues as diagonal entries.

3: The eigenvectors are already orthogonal. There is a process called Gram-Schmidt orthogonalization used to define a set of vectors that are normal to each other. These orthogonalized vectors form a convenient basis. Linear combinations of the basis vectors can produce any other vector in the same vector space; for the orthogonalized basis, the basis vectors are as independent as possible. Here, GramSchmidt produces vectors that are also normalized to unit vectors. This, and other useful vector functions such as Normalize are available for common vector operations.

4: The geometrical interpretation of this operation can be found by comparing a matching MatrixTransform to the matrix composed of eigenvector columns. Here, we see that eigenvector-matrix is equivalent to the π/4 rotation matrix.

6–7: These demonstrate that Eq. 9-2 is true.

8: This demonstrates that $A^n \vec{v} = \lambda^n \vec{v}$.
